Foreword
by Centre Director
The objective of SFI MOVE was to contribute to commercially solid and cost-effective marine operations, helping to position the Norwegian maritime industry in the market for such operations worldwide. Norway has a long coastline and a continental shelf that is six times larger than the mainland, constituting a third of the European continental shelf. Norway has a strong position in ocean industries such as oil and gas, fishing, fish farming and a growing offshore wind industry. Demanding marine operations are a common core activity in all these segments. 70% of Norwegian exports are from ocean-based industries, and marine operation is a core activity.

SFI MOVE was granted resources in 2014 and started the project in the autumn of 2015. The Faculty of Maritime Technology at Aalesund University College was the host. MARINTEK and SINTEF Fisheries and Aquaculture were research partners. Aalesund University College has become part of NTNU, and MARINTEK and SINTEF Fisheries and Aquaculture have become SINTEF Ocean. We were very pleased about the restructuring of the research partners in two strong organizations. SFI MOVE has been an instrument in building a unified understanding of marine operations. 20 companies have been involved in research activities in SFI MOVE.

The oil and gas industry and related maritime activity had 10 years of vigorous growth until 2015. Then the global economy faced one of the largest oil-price shocks in modern history. The 70 percent price drop and corresponding financial crisis generated shock waves in the maritime industry. Most oil rigs became inactive and 850 offshore vessels were laid up. The crisis had a dramatic impact on the suppliers and the maritime clusters.

Some partners closed and new partners joined SFI MOVE. Despite the tough economic situation, the industry is recovering, and we can see increased activity and optimism. In 2021–2023, driven by higher energy prices, supply disruptions, and sanctions, the petroleum sector had a growing significance on Norwegian GDP and government cashflow compared to previous years.

In this period, SFI MOVE tried to find a balance between activities that could enhance competitive strength in the short-term and long-term as well as between industrial innovation and scientific merits. I would particularly like to express my gratitude to the industrial partners contributing to SFI MOVE.

In the last period, SFI MOVE was working with the following three projects.

- Operational response in floating offshore wind installations and services
- On-board decision support tool for marine operations
- Remote operations

Results are summarized in this report. Several new projects transferring results from SFI MOVE have been launched.

SFI MOVE has produced 278 publications, 14 PhDs, 9 PD, and 33 scientific reports.

Hans Petter Hildre
Centre Director
Foreword
by Head of Host Institution
When NTNU merged with the Aalesund University College in 2016, the goal was to strengthen the competence within maritime disciplines and foster closer cooperation with industry. SFI MOVE has been an important instrument for bridging the maritime research communities in Trondheim and Ålesund. Common research projects and joint supervision of PhDs have been instrumental in building a unified understanding and development.

Norway has been a leading nation in ocean research and development. With a continental shelf six times the land area and the second longest coastline in the world, Norway has developed strong research and education institutions. Industries within fisheries, oil and gas services, and fish farming have been established. Now, we can see growing activity within offshore wind. Innovation in demanding marine operations has been the common driver for this development. The SFI Marine Operation in Virtual Environments is therefore at the core of this success factor bringing operations into a digital framework.

Now under construction, the Norwegian Marine Technology Centre will rank among the world’s most advanced facilities for research and education in marine engineering. The centre will provide NTNU and SINTEF access to world-class facilities and premises. The centre’s main location will be in Trondheim with wet and dry laboratories, workshops, teaching premises, offices, and meeting rooms.

Fjord Laboratory is a laboratory for full-scale experiments and research in the sea. Fjord Laboratory consists of various laboratories in water and on land, and is located in the Trondheimsfjord, around Hitra and Frøya, and in Ålesund.

I would like to take this opportunity to express my gratitude to all the colleagues, researchers, PhDs, postdocs, master’s students, partners, and collaborators who have contributed to creating competence, knowledge, and innovations in SFI MOVE. I would also like to emphasize the importance of the partnerships with SINTEF, Olympic Shipping, Ulstein International, Kongsberg Maritime, TechnipFMC, Subsea 7, Equinor, Havila Shipping, Havfram, DNV, Vard, NTNU Ocean Training, OSC and ÅKP. Together with NTNU, you have provided important support in terms of cash and in-kind contributions.

Finally, I would like to express my gratitude to the Research Council of Norway for designating us as a centre for research-based innovation and for providing funding. Their trust in our research has been instrumental in our success, and we are grateful for the support.

Olav Bolland
Dean, Faculty of Engineering
Summary

Text: Hans Petter Hildre
The overall objective of SFI MOVE is to facilitate commercially competitive and cost-effective solutions in marine operations, thus contributing to positioning the Norwegian maritime industry in the global market for such operations. As operations become more extensive, there is a need for more all-year marine operations. The need for all-year operations will significantly impact technology, operational procedures, and costs, and will require very different solutions depending on the operating environment. SFI MOVE contributions are summarized as follows:

### Contributions to improved simulation accuracy

In many cases, the limiting sea state depends on the hydrodynamic coefficients used in the analyses. Research has been done to improve the accuracy of coefficients and support project engineers in design and analysis of marine operations on a day-to-day basis. The purpose is of course to reduce waiting on weather.

**More accurate hydrodynamic coefficients**

Hydrodynamic coefficients for subsea structures and structure parts relevant for subsea lifting and installation operations have been developed. Libraries and a user guide have been made.

**Vessel shielding effects**

Methods for considering shielding effects from an installation vessel on a lifted object have been developed.

**Splash zone hydrodynamics**

Estimates of hydrodynamic coefficients in the water entry phase of elements of subsea modules have been developed. Libraries and a user guide have been made.

**Co-simulations**

Co-simulation in maritime operations has been explored. Co-simulation is modular by nature and highly flexible, whereby a full system simulation is built from several stand-alone sub-simulators. It leverages specialized toolchains and domain-specific knowledge already in use by participants and partners. Tools and domain knowledge within hydrodynamics can be combined with tools and methods within hydraulics, control systems, and so on.

### Contributions to on-board simulations

Marine operations are designed, simulated, and planned long before the operation is carried out. Parameters are assumed for the type of vessel, load condition, wind, waves, lifted objects' behaviour in air and sea, etc. The simulation results show that the operation can be carried out if a given sea state is not exceeded. Therefore, simulations are based on a series of assumptions and uncertainties. Significant safety margins are needed to compensate for these uncertainties.

SFI MOVE has several contributions for how to reduce waiting on weather by bringing the analyses close to the operations and defining operations by measured and predicted responses. Using a digital twin technology facilitates go criteria for the operations in terms of vessel or crane response rather than met-ocean parameters, which leads to more precise operational criteria.

**Digital twin concepts**

Digital twin concepts have been tested using the NTNU research vessel R/V Gunnerus. Responses were simulated based on present met-ocean as well as predicted future situations. Digital twin concepts have been tested using the NTNU research vessel R/V Gunnerus. Responses were simulated based on present met-ocean as well as predicted future situations.

**Data driven ship model tuning methodology and methods**

Two methods have been developed. First, based on spectral values of measured wave and ship motions on an operating vessel, the parameters of the theoretical ship model are adjusted to match the response of the theoretical model to the measured response of the operation vessel. Second, a machine learning algorithm is used to compensate for the error in the theoretical ship model. Both methods are tested and verified.

### Contributions to remote operations and handover from engineering to operations

Marine operations are increasingly technology based. New technologies such as digital twins, cloud computing and machine learning enable faster change and create more complex and dynamic work environments. The driver for such development is reduced costs by having remote support replacing human support on board. Advantages include increased quality through access to a broader variety of competence and reduced risk through capacities to perform advanced analytics and trade-off scenarios.

**Remote operation framework**

A remote operations framework can be established by adding a copy of the on-board digital twin to a remote centre. The sensors' signals will be transferred to the remote centre and all responses will be calculated by the digital twin. The idea is to have a single tool covering the process from engineering to handover to on-board to a remote operation centre.

### Contributions to response predictions

The aim of this activity is to improve today's methods for the prediction of vessel response for the execution of marine operations. Prediction can broadly be divided into two categories: short-term and long-term prediction. Short-term prediction means predicting the vessel's response a few minutes ahead. This is useful when a critical action of short duration is to be carried out. Long-term prediction (hours and days) is relevant for longer operations where the motion of the vessel must be kept within given limits. In both cases, good response prediction depends on good prediction of waves and other met-ocean disturbances and good response models.

**Case studies**

Case studies are used as an in-depth examination to explore opportunities within a real-world context. Challenges have been identified and used as an input to new research activities. Case studies have been used for both practical and theoretical issues. The cases have also been important to verify new theories and methods. The following areas for cases have been used throughout the project:

- Offshore mining
- Subsea lifting operations
- Installation of offshore wind
- Remote operations
Sammendrag
Tekst: Hans Petter Hildre
Det overordnede målet med SFI MOVE er å legge til rette for konkurranseedyktige og kostnadseffektive marine operasjoner, og dermed bidra til å posisjonere den norske maritime industrien i det globale markedet. Ettersom operasjonene blir mer krevente, øker behovet for mer helårs marine operasjoner. Behovet for helårs aktivitet vil ha betydelig innvirkning på teknologi, operasjonelle prosedyrer og kostnader, og vil kreve svært forskjellige løsninger avhengig av sjøtilstand, vind, havstrøm osv. SFI MOVEs bidrag oppsummeres som følger:

**Bidrag til forbedret simuleringens nøyaktighet**
De hydrodynamiske koeffisientene er sentral i å beregne maksimal sjøtilstand for å kunne gjennomføre en operasjon. Det er gjort forskning for å forbedre nøyaktigheten av koeffisientene og dermed støtte prosjektering i design og analyse av marine operasjonen i det daglige. Formålet er selvfølgelig å redusere ventetid på godt nok vær (WoW).

**Bidrag til simuleringer ombord i fartøyet**
Marine operasjoner blir designet, simulert og planlagt, lenge før operasjonen gjennomføres i virkeligheten. Parametre antas for en type fartøy, lasttilstand, vind, bølger, løftede objekters oppførsel i luft og sjø osv. Simuleringsresultatene viser at operasjonen kan gjennomføres hvis en gitt sjøtilstand ikke overskrides. Derfor er simuleringer basert på en rekke antagelser og usikkerheter. Betydelige sikkerhetsmargener er nødvendige for å kompensere for disse usikkerhetene. SFI MOVE har flere bidrag til hvordan man kan redusere ventetid på været ved å bringe analyser på realtidsbasert på en erhvervsspesifikk baseret på øvning.

**Mer nøyaktige hydrodynamiske koeffisienter**
Hydrodynamiske koeffisienter for undersvannsstrukturer og andre konstruksjoner relevant for undersvanns løftet- og installasjonsoperasjoner har blitt utviklet. Bibliotek og brukerveiledning er laget.

**Effekter av sjøring på le-siden av fartøyet**
Metoder for å ivareta effekten av sjøring på le-siden på installasjonsfartøy er viktige for å redusere ventetiden på båtets tilknytning.

**Skalpesonehydrodynamikk**
Estimat av hydrodynamiske koeffisienter i det objektet treffer vanntiliven på blitt utviklet. Fokuset har vært på vurdering av koeffisienter for "slambelastning" så vel som koeffisienter for dempning og tilleggsomstrukturering.

**Co-simuleringer**

**Bidrag til simuleringer ombord i fartøyet**
Marine operasjoner blir designet, simulert og planlagt, lenge før operasjonen gjennomføres i virkeligheten. Parametre antas for en type fartøy, laststabilitet, vind, bølger, løftede objekters oppførsel i luft og sjø osv. Simuleringsresultatene viser at operasjonen kan gjennomføres hvis en gitt sjøtilstand ikke overskrides. Derfor er simuleringer basert på en rekke antagelser og usikkerheter. Betydelige sikkerhetsmargener er nødvendige for å kompensere for disse usikkerhetene. SFI MOVE har flere bidrag til hvordan man kan redusere ventetid på været ved å bringe analyser på realtidsbasert på en erhvervsspesifikk baseret på øvning.

**Digital representasjon av marine operasjoner**

**Case-studier**
Case-studier er brukt til grundige mulighetsstudier innenfor en virkelig kontekst. Utfordringer har blitt identifisert og brukt som inngang til nye forskningsaktiviteter. Casene har blitt brukt både for praktiske og teoretiske utfordringer.

- Offshore gruvedrift
- Subsea løfteoperasjoner
- Installasjon av offshore vind
- Fjernoperasjoner

**Bidrag til responsprediksjoner**
Virksomheter har det som f.eks. et fagmiljø med standardiserte operasjonsprosedyrer som ikke er i stand til å behandle potensielle utviklinger. Responser kan brukes til å forutse fremtidige situasjoner.

**Case-studier**
Case-studier er brukt til grundige mulighetsstudier innenfor en virkelig kontekst. Utfordringer har blitt identifisert og brukt som inngang til nye forskningsaktiviteter. Casene har blitt brukt både for praktiske og teoretiske utfordringer.

Casene har også vært viktige for å verifisere nye teorier og metoder. Følgende områder for casestudier har blitt brukt gjennom hele prosjektet:
Vision and mission
Text: Hans Petter Hildre
Vision
To establish a world-leading research and innovation centre for demanding marine operations.

Simulation has been used for decades to plan and verify marine operations and to train crew to perform the operations. Next-generation technology has the potential to provide virtual prototyping to pre-test marine operations including human components. On-board and remote support simulation systems consider the real met-ocean situation and the ship’s real behaviour will reduce waiting on Weather and thereby reduce costs. Remote support has the potential to move experts from the ship to the land-based organization.

Cutting-edge interdisciplinary research will provide a bridge between industrial needs, innovation, and research.

Research
Our goal is to take a world-leading position within demanding marine operations.

Innovation
Our goal is to put the industrial partners in front of defining needs and potential for innovation and business.

Education
The research shall lead to theory and new methods for education as well as training of professionals.

Arena
The goal is to establish an arena for research and industrial cooperation within demanding marine operations.

Objectives
The SFI centre shall support the entire value chain for marine operations by developing knowledge, methods, and computer tools for safe and efficient analysis of both the equipment and the operation. The developed methods shall be implemented in simulator environments to pre-test marine operations including the human component.

The SFI centre shall support the innovation process of the marine operation value chain through active involvement by industry, thus improving the competitiveness of Norwegian marine industry. The centre shall:
- Achieve all-year subsea operations installation and service
- Perform safer and more cost-efficient operations
- Support innovation in existing and emerging ocean industries

The idea is to optimize operations, from planning to execution, by a better understanding of the responses. This is a simulation-oriented approach where models are reused throughout the value chain. To fulfil this goal, the following is of vital importance:
- Improved understanding of complex physical phenomena
- Modelling and Virtual Prototyping (simulation)
- Simulation as an industrial standard
- On-board decision support systems
- Online environment monitoring
- Improved crew performance (training and assessment)

Business areas
- Demanding marine offshore operations at deep water, all-year availability, or arctic areas
- Installation and maintenance of offshore wind
- Management of marine operations and shipping
Basic facts about the centre
From boom to crises in the offshore industry

The oil and gas industry and related maritime activity had 10 years of vigorous growth until 2015. Then the global economy faced one of the largest oil-price shocks in modern history. The 70 percent price drop over that period was one of the three largest declines since World War II, and the most persistent since the supply-driven collapse of 1986. Most oil rigs became inactive and 850 offshore vessels were laid up. The crises had a tremendous impact on the suppliers and the maritime clusters.

The offshore oil and gas industry paid a lot attention to cost reduction during the first years in the project period. We have seen significant restructuring of the offshore support business and efforts reducing costs have been top priority. Despite the tough economic situation, the industry is in recovery, and we can see increased activity and optimism.

Some partners ended their participation and new partners joined SFI MOVE. A significant change in focus was introduced as a part of the mid-way evaluations. We will therefore present basic facts for the first period and second project period separately.

Organization

The centre is organized with a Centre Director and a Centre Board approving research plans and follow-up activities. The day-to-day activities are managed by a Centre Research Leader Team and Centre Management.

A scientific advisory board assures research quality and an industrial advisory board gives advice regarding topics to be focused. The advisory board was very important in the transitions caused by the oil crises.
Main organization in the first period

Centre Management

- Hans Petter Hildre, NTNU
  Centre Director
- Magnhild K. Wolff, NTNU
  Centre administration

Centre Research Leader Team

- Svein Sævik, NTNU
- Henning Borgen, SINTEF Ålesund
- Karl Henning Halse, NTNU
- Frøy Birte Bjørneseth, NTNU

Research partner(s)
- NTNU
- MARINTEK
- SINTEF Fiskeri og Havbruk

Industry partners
- Farstad Shipping
- Olympic Shipping
- Havila Shipping
- Rolls-Royce Marine
- Ulstein International
- ÅKP/GCE Blue Maritime
- Offshore Simulator Centre, OSC
- Vard
- Cranemaster
- NTNU Ocean Training
- Statoil Petroleum
- EMAS AMC
- Ocean Installer
- Statoil
- DNV-GL

The Centre Board
- Torleif Sætrevik, Chairman (Statkraft)
- Thore Thuestad (Statoil)
- Tore Ulstein (Ulstein International)
- Guro Løken (EMAS AMC)
- Hans Petter Hildre (NTNU in Ålesund)
- Harald Ellingsen 2 (NTNU)
- Halvor Lie (Marintek)

Scientific Advisory Committee
- Odd Magnus Faltinsen, NTNU
- Torgeir M oan, NTNU
- Kazuo Nishimota,
  University of Sao Paulo (USP)
Main organization in the second period

**Centre Management**

- **Hans Petter Hildre**, NTNU, Centre Director
- **Magnhild K. Wolff**, NTNU, Centre administration

**Research partner(s)**

- NTNU
- SINTEF Ocean

**Industrial partners**

- Olympic Shipping
- Havila Shipping
- Kongsberg
- Ulstein International
- OSC
- Vard
- NTNU Ocean Training
- Equinor
- Havfram
- DNV
- Subsea 7
- TechnipFMC

**The Centre Board**

- Rafael Rossi, Chairman (TechnipFMC)
- Erling Myhre, (Equinor)
- Tore Ulstein (Ulstein International)
- Sverre Torben (Kongsberg, formerly Rolls-Royce Marine)
- Hans Petter Hildre (NTNU)
- Sverre Steen (NTNU)
- Harald Stenersen (Havila Shipping)
- Arne Fredheim (SINTEF Ocean)
- Runar Stave (Olympic)

**Centre Research Leader Team**

- **Svein Sævik**, NTNU
- **Egil Giertsen**, SINTEF Ocean
- **Karl Henning Halse**, NTNU
- **Marie Haugli-Sandvik**, NTNU

Research

Text:
Hans Petter Hildre
Svein Sævik
Karl Henning Halse
Egil Giertsen
Marie Haugli-Sandvik
For the mining industry, a shift from onshore to offshore operations would offer a large and growing resource potential. Present challenges also creating offshore opportunities include future lack of onshore resources, rare earth material challenges, geopolitical positioning, conflicting societal interests (environmental damage vs business). A large volume of resources is most likely available both inside and outside national waters, but there is very high uncertainty around the value of these resources. In Norwegian waters alone, an NTNU study estimates that a low estimate would be USD 75 bn, with no upper limit. SFI MOVE had a focus on the design of lift systems to allow efficient lifting of minerals from the seabed to the ship. New simulation models were developed, and the research activity was completed in 2019.

Virtual prototyping
The primary objective was to develop an open, standardized framework and architecture for system simulation and virtual prototyping. A key to achieving such functionality is an open framework, standardized interfaces, and generic models to be shared in the industry. The plan was to present methods and demonstrate the cycle from design to virtual prototyping as shown in Figure 1.

The idea was to close the gap between ship design, equipment manufacturers and marine operations. This shift will move simulation from a verification point of view to a design and operation point of view.

The virtual prototyping project was transferred to another initiative, the Open Simulation Platform, in cooperation with DNV-GL, Rolls-Royce Marine, SINTEF and NTNU. A cooperation agreement was signed on 3 July 2018 – see photo 1. Activities in SFI MOVE were merged into this project in 2019.

Original research plan and development of research plan
The project portfolio in the beginning of SFI MOVE was:
- Seabed mining
- Virtual prototyping
- Installation and service of offshore wind, bottom-fixed floating structures
- All-year subsea operations

The original research plan had a long-term research philosophy. The industry was experiencing high demand and did not express short-term needs. Then the global oil crises hit the industry. The 70 % drop in the oil price had consequences. The crises hit shipowners as well as suppliers and maritime industrial clusters involved in SFI MOVE. Businesses were closed and cost reductions gained focus.

SFI MOVE took this change into consideration to shift focus from long-term goals to a shorter horizon of research. The project portfolio and the content in the projects gradually changed from exploration and solving fundamental problems to low-cost operations. The focus turned to solving industrial problems and creating new tools and methods. The Industrial Advisory Group was heavily involved in this process in 2017 and 2018 and an innovation plan was made. The plan identified marine operations and industrial challenges to be focused on (voice of the user).

The shift, including budgets, was finalized as part of the mid-way evaluation in 2019. Two projects were stopped, two projects were redefined, and a new project was launched.

Seabed mining
The overall goal for this project was to explore technologies to develop seabed mining as a new business area. Seabed mining is a promising area but has not been prioritized by the companies due to restructuring and a strong focus on short-term business opportunities.
Installation and service of offshore wind, bottom-fixed and floating structures

Installation and service of bottom-fixed offshore wind power plants were booming in the beginning of the SFI MOVE project. The cost for a wind field was reduced by a factor of 50% over 2-3 years and reached a level where it became profitable without subsidies. The EU is likely to reach its target of 20% of total energy consumption from renewable energy sources by 2020. Their future target is to increase the amount of renewable energy to 50% by 2030.

Statkraft was at the forefront of this development in SFI MOVE. Installations were normally carried out with a jack-up ship and with high-lift cranes lifting the individual parts of the offshore wind turbine into place one by one. In total, this involves five individual lifting operations. The SFI's idea was to replace the jack-up with vessels and compensate for movement during the lifting operation. Statkraft changed its strategy at the end of 2015 and decided to work only with land-based wind power. It shut down its offshore wind activity and contribution to SFI MOVE.

Equinor was at the forefront of floating wind systems and new research plans for floating wind were set up. An important driving force was to handle bigger turbines to reduce cost. With fewer restrictions on size and height than their onshore counterparts, offshore wind turbines are becoming giants. 12 MW turbines were installed in 2019 and Siemens Gamesa’s massive 14 MW turbines produced their first electricity in 2021. The Siemens turbine has a rotor diameter of 222 metres and 260 metres high to the rotor centre. Even bigger units are in development.

Installations are moving further from shore, tapping better quality wind resources, and pushing up capacity factors. Next generation giant turbines demand new methods for installation, service, and repair. Installation of giant offshore structures is presently done using huge crane vessels with the required lifting capacities and height. Such assembly takes place in sheltered areas and the structures are then towed to the wind farm for mooring. This is a complex and costly operation.

The goal in SFI MOVE was to develop an innovative lifting solution using ships. The lifting force was to be attached at the lower point of the tower instead of using a huge crane higher than the wind turbine.

**All-year subsea operations**

The objective of SFI MOVE was to contribute to commercially viable and cost-effective marine operations, helping to position the Norwegian maritime industry in the market for such operations worldwide. As subsea field developments become more extensive, there is an increasing need for all-year marine operations. All-year operation will have a significant impact on technology, operational procedures, and cost, and will require very different solutions depending on the operating environment. There is a need for new methods, systems, and equipment to achieve the defined objective. Our aim was to establish a virtual prototyping (VP) approach for subsea operations.

Subsea installation and services have operational limitations due to environmental conditions such as waves, wind, currents, and water depth. In harsh environments, there will be operational limitations in performing marine operations.

Marine operations are designed, simulated, and planned long before the operation is carried out. Assumptions are made about the type of vessel, load condition, wind, waves, lifted objects’ behaviour in air and sea, etc. The simulation results show that the operation can be carried out if a given sea state is not exceeded. Therefore, simulations are based on a series of assumptions and uncertainties. Significant safety margins are needed to compensate for these uncertainties. How can we reduce this uncertainty and then reduce Waiting on Weather (WoW)?

This project was expanded to include on-board support as well. Waiting on Weather can be reduced by bringing the analyses close to the operations and defining operations by measured and predicted responses. Using a digital twin technology facilitates go criteria for the operations in terms of vessel or crane response rather than met-ocean parameters, which leads to more precise operational criteria.

Data from ship sensors combined with physics-based models are used to monitor and predict responses of the vessels and equipment used in the operation. Simulations will be performed in almost real-time and give advice to the crew performing a marine operation on how to operate safely and efficiently. The idea is to bring the analyses close to the operations and decisions based on actual responses. The simulations can be performed on board the ship or in remote operation centres. The sensor data from the ship then needs to be transferred to the remote operation centre. The technology developed will make an important contribution to response-based operations. This approach also links the simulation in the engineering phase to the operations phase.

**Remote operations, a new project**

The Centre Board wanted to pick one more project from the Innovation Plan as a new project from 2019. The project Remote Operations/Dispersed Crew was initiated. This project also supports the key objective for the Centre. The purpose is to increase relevance and stimulate industrial interests. The content of the projects is gradually changing from exploration and solving fundamental problems to using results to solve industrial problems and create new tools and methods.

Marine operations are becoming increasingly technology based. New technological solutions such as digital twins, cloud computing and machine learning enable faster change and create more complex and dynamic work environments, which is followed by organizational changes, and implementations of new and more flexible structures and ways of working. The driver for such development is reduced costs through remote support replacing human support on board, as well as increased quality through access to a broader variety of competence and reduced risk through capacities to perform advanced analytics and trade-off scenarios. A remote operations framework can be established by adding a copy of the on-board digital twin to a remote centre. The sensors’ signals will be transferred to the remote centre and all responses will be calculated by the digital twin. Having a twin and simulation capacity at the remote centre gives several advantages.

- Low demand for transmission bandwidth
- Alternative scenarios can be executed while the ship is waiting
- The users in the operation centre can choose their view of interest

**Summary of projects in the last period**

The last period was planned by specifying final deliveries for the SFI MOVE.

1. Established a leading research and innovation centre for demanding marine operations
2. System simulation workbench for real responses:
   A. Modular set of models allowing simulation of subsea operations and offshore wind installations (Functional Mock-up Interface (FMI) Functional Mock-up Unit (FMU) modules)
   B. Ship behaviour and data driven tuning of ship models
   C. Prediction of future weather responses
   D. Backbone of simulation capabilities from sales, engineering, on-board and remote operations
   E. Front-end modelling and visualization environment
3. Methods and set-up for remote operations (based on simulation)
4. Demonstrators of technology. On-board and remote operations demonstrated for R/V Gunnerus and an offshore vessel (case: subsea lifting/installation)

In the final period, the work was concentrated in three projects. Final delivery for each project was defined and a roadmap defining year-year milestones was defined as shown in Figure 2.
**Project: Operational responses in floating offshore wind installation and services**

**Final delivery**
Simulation workbench for offshore wind installations.
A novel design for floating offshore wind.

**Project: On-board decision support tool for marine operations (subsea lifting operations)**

**Final delivery**
ODSS for subsea lifting operation. From lift-off to landing.
Simulation tool covering areas from sales through engineering, to on board and remote.

**Project: Remote operations**

**Final delivery**
Full demonstrator of remote operations and dispersed team.
A remote operation centre implemented as a demonstrator at NTNU.
Research achievements

Ocean Mining
The sub-project on ocean mining focused on the dynamic response of the riser needed for vertical transport of the ore material from the seabed to the vessel, as a basis for calculating the fatigue life, limiting the time window within which such operations can take place. The project was carried out as a collaboration between the Department of Marine Technology and the Department of Energy and Process Engineering at NTNU.

A 1D time domain riser flow model that included the water, stone and gas phases was developed and integrated by means of a full two-way coupling to the Riflex software for global dynamic analysis of riser systems. Meanwhile a time domain load model for Vortex Induced Vibrations (VIV) was also implemented into the same framework such that the effects from both internal flow, 1\(^{st}\) order wave kinematics and VIV on riser fatigue could be investigated in the same model.

The model was then applied to perform a case study on a steel riser for vertical transport, taking the Loke’s Castle site outside Svalbard as a basis for selecting input parameters. The case study showed that the internal flow coupling might both increase and decrease the riser fatigue, depending on how the flow density waves are synchronized to the VIV motions, thus having the potential of controlling to some extent the weather window available for the ocean mining operation.

Installation of Offshore Wind Turbines (OWT)
The work in this sub-project was split between short-term and long-term activities. Since the offshore wind energy market is completely dominated by bottom-fixed installations, some short-term activities related to bottom-fixed OWTs were started initially. More long-term activities related to the installation of floating OWTs were also initiated, since it is expected that the development of offshore wind installations will tend to move towards deeper water, where bottom-fixed OWTs will be less realistic.

Installation of bottom-fixed OWTs
As an associated work to the SFI MOVE project, Yuna Zhao has in her PhD work studied the modelling and analysis of the installation of offshore wind turbine blades. The feasibility of floating installation vessels for single blade installation is studied by comparing the motions of the blade root relative to the monopile top for jack-up, mono-hull and semi-submersible floating installation vessels, as shown in Figure 5. The Morison’s formula for hydrodynamic loads, the flexibility of the legs and the soil-pile interaction are considered for the jack-up vessel model, while the first- and second-order wave loads, and a dynamic positioning system were considered for the mono-hull and the semi-submersible floating installation vessels. The comparison indicates that the large-displacement semi-submersible has slightly higher motions of the blade root as compared to the jack-up vessel, while for the mono-hull installation vessel the blade root motions are too large. It is more feasible to use the semi-submersible than the mono-hull vessel for blade installation. Her work established a solid foundation for the PhD studies by Amrit Verma and Zhengru Ren, which were both conducted as part of the SFI MOVE project.

**Figure 4.** The physical quantities governing the dynamic loads during multiphase flow.

![Diagram](image3.png)

**Figure 5.** Offshore wind turbine installation using three different kinds of crane vessels: semi-submersible, mono-hull and jack-up. (From Zhao et al. (2019)).
In his PhD work, Amrit Verma studied the possible structural damage to the turbine blades from impact situations during the installation. Single blade installation in a lifting operation using jack-up and floating crane vessels was studied with a focus on blade root impact (operational loads) and leading edge impact (accidental loads). A high-fidelity finite element model based on solid elements was validated with experimental results. Damage assessment of the turbine blades was carried out to establish failure criteria. Based on the established failure criteria, global response analyses were performed to assess the limiting sea states for blade installation. A mitigation measure was proposed by placing a passive tuned mass damper on top of the monopile. This was found to reduce the impact velocity between root and hub significantly, which can substantially increase the operability of the blade mating operation. A case study was performed to display the merit of the proposed methods. The mitigation method enables the operational limiting curve and operability to increase by 40% using the proposed methodology.

Zhengru Ren studied control strategies to support the installation of offshore wind turbines in his PhD study. His focus was on the installation of blades for bottom-fixed offshore wind turbines using a jack-up vessel. He studied the whole lifting process of turbine blades from the deck of the jack-up installation vessel and up to the nacelle where they were safely mated to the hub.

A modularized simulation toolbox for the purpose of control design for single blade installation by crane operation was developed in MATLAB/Simulink. Based on the developed toolbox, an active tugger line tension control was proposed and demonstrated to be very effective in reducing the relative motion between the blade root and the hub during the final mating phase of the installation. Through well-tuned weighting matrices, the non-linear model predictive controller (NMPC) can prevent snap loads and axial peak tension, while ensuring a safe and efficient lifting operation. Automatic control theories were used to optimize the blade installation operation by minimizing the relative motion between the blade root and the hub. Global positioning systems (GPS) were integrated with an inertial measurement unit (IMU) to provide high-fidelity hub motion estimations.

Installation of Floating Offshore Wind Turbines
An initial design of a floating installation vessel (a catamaran hull) together with an initial design of a low-height lifting mechanism was proposed in 2016. This included a gripper mechanism to reduce the relative motion between the floating installation vessel and the moored floating SPAR substructure and a hydraulically controlled lifting mechanism. The main concern with this concept was the high contact forces involved (in the gripper mechanism as well as in the lifting mechanism) to reduce the relative motions between the OWT and the spar-shaped substructure.

An improved concept was proposed to reduce the interaction forces necessary to limit the relative motion between the OWT and the SPAR substructure. The lifting mechanism was updated and mounted on a motion-compensated platform which was designed to follow the wave-induced motions of the SPAR buoy. Following this approach, the concept evolved to an alternative where the OWT is held by a set of lifting wires and balanced by a set of stabilizing wires (see Figure 8). The relative motion is controlled by active winch control.
Inspired by the knowledge of inverse dynamics and range-based localization, a model-free controller was developed. It has a simple control design and the freedom from building the control allocation matrix.

The concept was improved in several steps. The relative motion between the moored floating SPAR substructure and the DP-controlled floating installation vessel was reduced by introducing a fender system in combination with a pretensioned wire system to keep the two floating bodies in tight contact.

The main challenge for the proposed concept was to reduce the relative motion between the lifted OWT tower and the floating substructure (the SPAR buoy). Several case studies were completed to support the performance of the simulation workbench.

A mechanical damping device (consisting of fenders and pretensioned wires) was introduced between the floating SPAR buoy and the vessel, to reduce the relative motion (see Figure 8). The spring stiffness of the fender and the pretension in the wires were varied to study the effect on the system response.

1. A finite element model of the jacket-like crane structure with realistic stiffness properties (or flexibility) was modelled and simulated in a dynamic analysis. The dynamic response of the crane top was compared to the response from simulations where the crane was assumed to be a part of the rigid body motion of the vessel.

2. The pitch motion of the catamaran is one of the dominating factors to influence the relative motion between the SPAR and OWT, and in order to overcome the effect of the pitch motion, an alternative installation concept at the midship was proposed. A comparison study where the mating point was located at the stern of the catamaran, at the side of the catamaran (approximately at the midship) and in the centre of the catamaran was carried out; see Figure 9.

3. The preliminary conclusion from our initial operability analysis with the alternative concept is that the operational limits are significantly increased if we move the installation to the midship or the side. The side installation may introduce new challenges (e.g. from static inclination or roll motion), but the alternative installation concept is promising.

4. A comparative study with an alternative installation vessel (a small water-plane area twin-hull vessel (SWATH)) has been completed. The conclusion is that the response of the SWATH is less than the catamaran and consequently that the relative motion between the vessel and the SPAR is reduced.

5. A quick connection device between the OWT and the SPAR is designed to reduce the time needed for mating of the OWT and the SPAR. Analyses were performed to study the impact loads between the two objects during mating.

Modelling issues

During the design of the proposed installation concept, several software tools were used to assess the dynamic behaviour of the system. The hydrodynamic behaviour of the floating objects (the installation vessel and the spar-shaped substructure) has been established using the HydroD module Wadam. Dynamic analyses of the coupled system have been carried out using both SIMO and Orcaflex, both of which have excellent models for including the hydrodynamic characteristics of the floating objects. However, the functionality to model and analyse complex mechanical/hydraulic systems are less developed in these software systems. Other tools (like AGX) have excellent models for the mechanical/hydraulic systems but are less flexible with respect to include proper hydrodynamic models. Furthermore, most of these software systems lack the functionality to include realistic models for advanced control systems.

Simulation workbench for wind turbine installation systems

To overcome these challenges, a co-simulation approach was adopted. Co-simulation techniques allow for a combination of various specialized domain tools to act together in concert. To succeed with the co-simulation approach, one need to:

- ensure proper connectivity between the FMUs (avoid tight coupling problems)
- ensure both dynamical and numerical stability of the system
- reach a satisfactory accuracy by using proper communication time step
- and to be useful in an on-board decision support system, close to real-time behaviour must be ensured
The co-simulation approach was tested on a simplified system to achieve control with the approach and address the various challenges mentioned above. Based on this, the computational performance was improved significantly by using the software AGX to make the FMUs instead of the initial OrcaFlex attempt.

A preliminary modularization solution was developed for the FMI-based co-simulation of the whole system, see Figure 10. Separate FMUs are made for the OWT, vessel, and spar based on OrcaFlex. Secondary controlled winches are packaged as FMUs in 20-sim for the lifting and stabilization. In addition, controllers involving simplified control algorithms are made as FMUs for winch control and dynamic positioning (DP) control, respectively. The Vico platform developed by NTNU in Ålesund was applied to test the co-simulation performance. All the FMUs are parameterized and connected with each other based on system structure and parameterization (SSP) standard. The results have been compared with the relevant monolithic simulation, and although there are some accuracy and efficiency issues, the results so far are promising.

In an attempt to shelter the installation process from waves, SFI MOVE introduced a large “floating dock” concept. The floating dock concept is intended to shield a spar floating wind turbine during installation of the tower, nacelle, and rotor onto the spar foundation. First, design optimization of the dock was performed to minimize the material cost. During the optimization, multiple design variables and non-linear constraints imposed by operational and transit conditions were addressed; see Figure 11. Then, hydrodynamic analysis and dynamic response analysis of the coupled system of the dock and the spar were conducted.

As part of a PhD work by Maël Moreau, a potential code was developed for the floating dock and a floating spar inside. The code also includes empirical estimates of the viscous effects inside the dock where internal baffles are designed to increase the hydrodynamic damping of the floating dock. Model tests were carried out to understand
the behaviour of the floating dock in waves. The sloshing induced motions of a floating wind turbine’s spar inside the cylindrical floating dock were investigated for both regular and irregular incident waves. The reduction of the lowest natural sloshing frequency was a notable consequence of adding the spar inside the dock. Analytical results were compared to experimental results with a fair agreement, revealing a significant sensitivity of the amplitude of the motions to the moment of inertia in pitch of the dock, and to few other parameters related to the mass distributions and the geometries of both the spar and the dock. Various damping devices (both solid and perforated baffles, see Figure 12) have been tested with encouraging results. The solid baffle at small submergences damped the sloshing waves the most efficiently, reducing the resonant peak by more than 55%, which could help to meet the required criteria for the assembly of floating wind turbines in site at operational weather conditions.

Short-term deterministic forecasting of wave fields

The main objective of this activity was to improve the safety and efficiency of marine operations. Three alternative approaches were followed:

• Very short-term (tens of seconds) prediction of waves. When the stochastic weather forecast is not satisfactory, the deterministic forecast of waves may discover short openings in otherwise closed weather windows (see Figure 13). The weather forecast is based on measurements from a wave radar. It is not possible to deterministically predict the sea surface elevation for the entire ocean. The predictable zone depends on the size of the measurement zone and on the group velocities of the shortest and longest waves. This may allow for marine operations to be performed – leading to all-year-round marine operations.

• Very short-term prediction of wave-induced motion. Based on measurements of the vessel response, (as well as measurements of the present sea state) the numerical model of the vessel is tuned by a neural network to minimize the prediction error, thus allowing the vessel model to better represent the hydrodynamic characteristics of the vessel. This will allow for more accurate predictions of the vessel response and open for safer execution of marine operations.

• From radar images, updated and actual wave spectra can be established. This may be an important contribution in planning of marine operations and in on-board decision support systems. More accurate assessment of the safety margins for the next few days can be found by using tuned numerical models.
**On-board Decision Support Tool for Marine Operations**

The on-board decision support system (ODSS) effort in SFI MOVE has developed knowledge, methods and technology on how to use operational data from ship sensors, combining these with physics-based models, to monitor and predict the response of the vessel and its working tools (e.g., lifting equipment), and based on this information, to give advice to the crew performing a marine operation on how to operate safely and efficiently. The technology developed will make an important contribution to response-based decision making in marine operations. The work undertaken in the ODSS effort has consisted of a mixture of activities linked to three of the original MOVE research areas: “Vessel performance” (RA1), “Enhanced physical modelling, numerical methods and tools” (RA2) and “On-board systems” (RA3).

**On-board decision support system (ODSS) architecture**

The work conducted in the on-board decision support system architecture activity has been ongoing since SFI MOVE started in 2015-2016. In 2018 and early 2019, basic concepts and architecture of the framework was formulated, illustrated in Figure 14. Examples of framework components were implemented, and at the 2019 MOVE Autumn Conference a simulation fed with real-time measurements was demonstrated. The simulation can be combined with “virtual sensors” that provides additional information which are not available through direct monitoring. This was demonstrated in the context of the “load in air” phase of a lifting operation. At the 2020 MOVE Autumn Conference another piece of the puzzle was demonstrated, namely how predictive simulations can give useful information about the limiting criteria for an operation. In this demonstration the focus was on the “load in splash zone”. In 2021 the focus was geared towards adaptive vessel models, where historical and/or live measurements were used for tuning key vessel parameters to improve both the system understanding as well as the operational safety and to increase the available operational window.

In 2022 the work on writing a document named “An architecture for on-board decision support systems” was started. A rough draft was distributed to selected industry partners for review and feedback, and the report was finalized in March. This report summarizes the work and findings from the ODSS architecture activity. It is believed that this document can become a solid foundation for the next stages of development, e.g., as spin-off innovation projects with the goal to lift the ODSS architecture research results to an industrial product. In addition to a description of the architecture, the document includes several case studies that demonstrate and validate the flexibility and robustness of the approach and design.

![Figure 14. Main components and interfaces in an ODSS architecture.](image-url)
Data driven ship model tuning methodology

In the earlier years of SFI MOVE, the model tuning method and software have been tested with data from laboratory model tests and simulations. Havfram AS has made a large amount of measured (“real”) data of motion and waves from the offshore service vessel Normand Vision available. In addition, field experiments with the vessel R/V Gunnerus were carried out in 2021 and 2022. The wave data experienced by the two vessels were measured with wave radar, which also provides information of the directional spreading. A numerical model for Normand Vision exists from previous years. For R/V Gunnerus a numerical model was established and reported in 2022. Both models are ready for tuning.

The amount of data from Normand Vision is large and was recorded continuously in time, regardless of what the vessel was doing (i.e. during transit, when loading at quay as well as during operations). In 2022 a considerable effort was used to find the time intervals when the data were relevant from a marine operation perspective and of good quality at the same time. This work is described in a separate report. The data from R/V Gunnerus were measured during a planned offshore campaign, and all the data are relevant and suited for tuning.

An important goal for the work in 2023 has been to see if wave data obtained with radar can be used for model tuning. It must be expected that considerable uncertainty exists in the wave spectra. The measured vessel motion, on the other hand, is of good quality. The numerical model has some initial uncertainties. In general terms the measured wave spectra are useful, therefore, only if they are “less uncertain than the parameters of the initial model”.

Vessel shielding effects

In 2020 the important task of establishing a method for including vessel shielding effects on a lifted object was started. During 2021 a prototype version of this method was implemented in the simulation tool SIMO. The new method and implementation were presented at the 2021 MOVE autumn conference, using the Johan Sverdrup ITS installation as case study, where the ITS (the lifted object) consisted of a number of slender elements. It was demonstrated that the shielding effect significantly reduced the tension in the main wire as compared to previous analysis which did not take this effect into account. In addition to taking the shielding effect into account, the new method uses a new and more efficient calculation method, and for the mentioned ITS installation analysis the total simulation time was reduced by approximately 50 % compared to the previous analysis. This will be an important feature to incorporate in numerical tools forming the basis of predictors to utilize the shielding effect the crane vessel will have on lifted objects.
Hydrodynamic coefficients for subsea structures

The activity on hydrodynamic coefficients has been ongoing throughout the MOVE project period. In 2021 the focus was on how the subsea equipment inside a module with protection roof and mudmat influence on the hydrodynamic coefficients. The main findings are that for the generalized modules tested, damping is generally the dominating hydrodynamic force. However, the presence of content inside the module will increase the importance of added mass compared with a module consisting of only roof and mudmat. Estimation of coefficients by summation of the coefficients for the individual structure parts was also studied. It is seen that the damping will generally be overestimated when estimated as the sum of the damping for the individual elements, compared with model test results of the entire module. If the module consists of both mudmat and roof, with and without internal content, estimation of added mass by summation is good. On the other hand, for structures without a roof or a mudmat, estimation by summation will underestimate the added mass.

To obtain good numerical models of an installation operation with reliable results, realistic hydrodynamic data for the structure to be installed are crucial. Based on old MARINTEK model test results from 1985 to 2013, added mass and damping for subsea structures and structure parts have been collected and presented in three SFI MOVE reports for future use.

Guide on numerical modelling and simulation of offshore lifting operations

Numerical modelling and simulations of the deployment of complex subsea structures are used to obtain limiting sea state for the operation and to assess forces in the lifting equipment and on the structure. Based on earlier experience and knowledge obtained in the MOVE project, a first version of a report with advice and examples that may be useful in the development of such numerical models was delivered at the end of 2019.

![Guide on numerical modelling and simulation of offshore lifting operations.](image-url)

Laboratory set-up for hydrodynamic testing of a different substructure.

The three reports summarizing the work on hydrodynamic coefficients.
The report is not intended to be a complete user’s manual or recommended practice for numerical modelling of installation operations. The main topic is estimation of hydrodynamic coefficients for subsea structures and how to model them. That said, some additional tips and tricks from experienced users regarding modelling of the complete system with vessel and lifting gear are included. Examples are given of how hydrodynamic coefficients for the structure to be installed may be estimated based on published data. It is shown how a suction anchor may be modelled by use of the slender element model in SIMA and how depth dependency of the coefficients may be used for splash zone crossing. Calculation of slamming forces by use of the slender element model and depth dependent coefficients are considered. Estimation of extreme response by use of the stationary approach and from lowering simulations are illustrated.

Snapshots from CFD simulations and model tests from forced-motion simulation/tests. Left; Suction anchor above the surface at the end of motion cycle. Right; Suction anchor below the surface at the end of motion cycle.

New findings and knowledge during the last years of MOVE, focusing on practical numerical modelling of installation operations, were added during the period 2022-2023. A revised version of the report was delivered in May 2023.

Splash zone hydrodynamics

The activity on splash zone hydrodynamics has been ongoing since 2020. The work in 2022 mainly focused on suction anchors and modelling of hydrodynamic forces for such structures in SIMO. SIMO models need hydrodynamic coefficients to estimate the corresponding hydrodynamic forces. Estimation of hydrodynamic coefficients were performed using both model tests and CFD (Computational Fluid Dynamics) in the free surface zone. Wave tests were also performed to have validation data for excitation forces when the SIMO model was examined. Snapshots from model tests and CFD simulations are shown below. In the CFD simulations 1/4th of the suction anchor was modelled due to double symmetry.

A SIMO model has been prepared to use the calculated hydrodynamic coefficients for simulations of the suction anchor in waves. Extensive studies were performed using WAMIT (Commercial code for computation of hydrodynamic forces) to examine the SIMO model for estimation of excitation forces near the free surface. In 2023 the splash zone activity, with suction anchor as case, was further pursued to come up with a model with acceptable accuracy to be shared with the industry partners. The results of the CFD simulations, model tests and SIMO model was reported in 2023.

Parametric seakeeping optimization tool

The aim of the seakeeping optimization tool activity has been to provide a tool to simplify the optimization of ship motion characteristics and to improve seakeeping performance for specific operational tasks and sea areas. This mission-dependent optimization approach involves adjusting hull dimensions and loading conditions, to ensure that important responses like pitch and roll are distinct from dominant wave periods. The approach can also be utilized in the on-board decision support context, allowing a more accurate prediction of the loading condition dependent roll response. In 2022 the seakeeping optimization tool for parametric studies was further developed and tested. The parametric vessel optimization tool is integrated in the existing seakeeping code VERES and is now available to project partners as updates to the ShipX 4.2 workbench.
Identification of the best vessel for efficient task execution

**Mission oriented vessel performance evaluation process**

**Vessel Response Optimization Framework (1/2)**

**Motivation:**
- Efficient and user-friendly comparison of task-related motion responses

**Objectives for designers:**
- Identify optimal vessel characteristics regarding
  - Main dimension properties
  - Load condition coefficients
  - Motion damping (RRT, bilge keels, fins)
- Considering designated site-specific mission aspects

**Objectives for operators and contractors:**
- Identify the best suitable vessel for efficient task execution
  - Considering mission aspects such as
    - Motion limitation criteria
    - Site-specific dominating wave periods from seasonal hindcast data
    - Range of achievable load-conditions through ballasting during mobilization

**Vessel Response Optimization Framework (2/2)**

**Scope of work:**
- Development of an optimization tool for parametric vessel motion comparison (more versatile and vessel specific than the earlier developed Vessel Response Tool)
- Development of a Parameter Study and a Vessel Response RAO Generator plugin within the new ShipX framework
- Implementation of the calculation of the Operability Robustness Index (ORI) as additional performance indicator
- Development of tailored post-processor solution to better compare many calculation results

**Deliverables:**
- New release of ShipX (available in ShipX version 4.3)
- Technical note on the new features

**Vessel Response Tool**

A Showcase for Response-Based Design Optimization
Open-access on [vrt.sintef.no](http://vrt.sintef.no)

**Parametric seakeeping optimization tool.**
Remote operations and dispersed teams

This project on remote operations focused on how use of digital twin technology can enable collaboration between shore and vessel, development of cyber security solutions, and how dispersed teams and digital transitions in remote operations can optimize workflow and organizational change. The focus was on how technological development in the maritime industry creates opportunities for optimization and increased safety in marine operations.

Project activities were structured using the HTO framework (Human-Technology-Organization), and the research activities have centred on data collection from simulator experiments, collaboration with industry partners, site visits, development of new business models and cost-benefit analysis. Amongst other things, we have tested our Remote Operation Centre (ROC) and digital twin technology, developed a cyber security course for maritime managers, and investigated new business models for remote operations. In 2021, we made a promotion video of our ROC and digital twin of the research vessel Gunnerus (link to video: https://www.youtube.com/watch?v=l0Yw6m3pM).

The final deliveries presented below are the case deliveries within the following main project activities: testing of ROC and situational awareness, business case, and technology and cyber security.

Testing of ROC and situational awareness

Within this project, simulator experiments were conducted during 2021 and 2022 with use of NTNU’s ROC and research vessel Gunnerus. The objectives of these experiments were to test usability, communication solutions, and situational awareness in the simulator set-up. The scenarios chosen for the experiments were executed in real time with use of our digital twin, R/V Gunnerus and nautical students.

Results of the simulator experiments showed that integration of sensor data can enhance usability if the interface is adjusted to the needs and competences of the operator. When we tested the communication between the ROC operators and the crew on R/V Gunnerus, the results indicated that existing communication solutions (voice/video/chat) can make it possible to solve a simple task. However, there is a need for more integrated communication solutions if the tasks at hand are complex and the collaborating team members (onshore and offshore) are highly dependent on each other.

The project successfully tested the remote operation centre set-up in real time and has provided evidence of the opportunities with use of sensor data and digital twin technology to enhance certain aspects of marine operations. This concept is still a work in progress, and we aim for additional research projects to fully comprehend the opportunities and challenges by introducing more remote ways of working within the maritime domain.

Business case

Extensive research has been conducted to examine the impact of remote operations in the maritime industry on organizational models and the relationships between ships, shipowners, and third-party suppliers. It has been established that remote operations introduce new
Preparing for cyber security drills in maritime bridge simulators. From R/V Gunnerus to the ROC was completed during this project. System performance and front-end designs were tested in the simulator experiments mentioned above.

The results showed that the system performance was sufficient to run scenarios in real time, but we experienced occasional loss of signals due to topography and 4G coverage. The visualization of sensor data provided the ROC operators with information about the environment and ship performance. Even so, we found that there is a need for further development of operator-specific dashboards and a change of placement of information sources. Future work should address how the remote operation centre can be more technically resilient, look at development of operator-specific dashboards, and investigate integrated communication solutions.

With increasing digitalization and connectivity in marine operations, the cyber-attack surfaces expand. This requires a holistic approach to cyber security in all phases of marine operations. We conducted research on maritime decision-makers’ perception of cyber risks, and the results showed that it is important to understand human behaviour to develop targeted cyber risk management strategies. This work contributed to the development of a maritime cyber security course, which was given to maritime personnel during January and February 2023. The focus of the course was on cyber security basics, cyber risk analysis, and training on cyber-attacks in maritime bridge simulators. We received very positive feedback from the participants in the course.

Technology and cyber security

Another focus of this project on remote operations was on technology development and cyber security training. The work with transferring and visualization of sensor data

Use of sensor data for decision support and predictions in ROC.
Highlights of scientific results

Ocean mining

Ocean mining
An analytical model based on modal analysis was developed for evaluating the structural response for a vertical ocean mining riser due to the density waves that may occur during the hydraulic lift operation.

This was followed by developing a prototype numerical model for evaluating the non-linear ocean mining riser dynamics in time domain considering a full two way coupling between the internal two or three phase flow and the external loads, the latter also including Vortex Induced Vibration related loads. The prototype model developed as part of the project is still beyond state of the art in 2023.

The work resulted in 3 conference papers, 4 conference presentations and 1 journal paper. In addition, 3 conference and 12 journal papers were associated to the project.

On-board decision support system (ODSS) architecture

A specification forming the basis for possible future developments of industrial ODSS systems based on the proofs of concept developed and presented at the SFI MOVE conferences has been produced as a documentation of the developed ODSS concept. This specification has been accompanied by case studies that demonstrate and validate the flexibility and robustness of the approach and designs.

Data driven ship model tuning methodology

Based on spectral values of measured waves and ship motions on an operating vessel, the parameters of the theoretical ship model are adjusted to match the response of the theoretical model to the measured response of the operating vessel. The tuning methodology has been tested on high-precision data from basin model tests in 1-D waves, in addition to full-scale 2-D wave spectral data and vessel motion data from the offshore support vessel Normand Vision (Havfram AS) and the smaller research vessel Gunnerus (NTNU).

Vessel shielding effects

Functional specification of method for taking into account shielding effects from an installation vessel on a lifted object has been developed. Numerical implementation and demonstration of the method for a relevant case has been performed and documented.

Hydrodynamic coefficients for subsea structures

To assist the project engineers designing and analysing marine operations on a daily basis, hydrodynamic coefficients for subsea structures and structure parts relevant for subsea lifting and installation operations have been collected from SINTEF Ocean’s historic model test activity and made available for the SFI MOVE partners.

To gain more knowledge of the nature of the hydrodynamic forces on the structures, a comprehensive series of model tests establishing hydrodynamic coefficients for generalized subsea structures and structure parts has been performed. These model test results give valuable knowledge on how to use available data and estimate hydrodynamic coefficients for use in analysis of installation operations.

Guide on numerical modelling and simulation of offshore lifting operations

A modelling guide based on SINTEF Ocean’s historical experience in numerical modelling of marine lifting operations, supplemented with the knowledge obtained on hydrodynamic coefficients, has been delivered.

Splash zone hydrodynamics

Model test data and commercial numerical codes have been used to come up with estimates of hydrodynamic coefficients in water entry phase of elements of subsea modules such as hatch covers, mudmats and their combination with other elements. Focus has been on estimation of slamming load and coefficients as well as damping and added mass coefficients at small submergence. Time domain simulations have been performed and compared with model test data and measurements to assess the accuracy of the estimated coefficients.

Parametric seakeeping optimization tool

SFI MOVE researchers have developed a tool for holistic ship design optimization, enabling ship designers to optimize ship motion characteristics and thus seakeeping performance for defined operational tasks and sea areas by performing a parametric variation of the main vessel particulars as well as loading condition parameters. The focus of the development has been on a fast and easy to use tool which makes use of existing seakeeping codes, and the tool has been developed as part of the ShipW-SIM A workbench. In an on-board decision support setting, the tool can be used to find the optimal loading condition for the ship for performing the intended operation in the forecasted weather.

Remote operations and dispersed teams

Finn Torle Hølmeset contributed to installing sensors and transferring sensor data from the research vessel Gunnerus to NTNU’s remote operation centre in Ålesund, which made the real-time testing of the simulator experiments possible. Bjarte Parelussen, Frey Birte Bjørneseth and Marie Haugli-Sandvik developed simulator scenarios for testing of the remote operation centre and the digital twin of R/V Gunnerus. These experiments provide the foundation for further development of scenarios to test how onshore and offshore crew can develop a distributed situational awareness in complex marine operations. Marie Haugli-Sandvik was one of the initiators and developers of a maritime cyber security course with scenarios for cyber security training in maritime bridge simulators, providing the groundwork for future courses within this topic.

Offshore wind installations

Installation of offshore wind is normally carried out with a jack-up ship and with high-lift cranes lifting the individual parts of the offshore wind turbine into place one by one - in total, 5 individual lifting operations. The crane tip is higher than the objects to be lifted. Wind power fields are moving further from shore, tapping better quality wind resources, and pushing up capacity factors. Offshore wind turbines are becoming giants. Siemens Gamesa’s massive 14 MW turbines produced their first electricity in 2021. The Siemens turbine has a rotor diameter of 222 metres and is 260 metres high to the rotor centre. Even bigger turbines at 20 MW are in development. Next-generation giant turbines demand new methods for installation, service, and repair. SFI MOVE has suggested a “low lifting mechanism”. The tower, nacelle, and blades are lifted on the floating part in one single operation. The heavy lifting is done with a low crane and wires attaching the lower part of the tower. The lifted unit is balanced by additional wires at a higher point on the tower.
International cooperation
Text: Hans Petter Hildre
The MOVE Centre has a strategic cooperation with the University of Sao Paulo (USP) in Brazil. The key person in contact is Professor Kazuo Nishimoto. USP is combining marine research and nautical operations and has a similar approach to the one we have defined in SFI MOVE.

A cooperation agreement was signed in 2016; see Photo 1. Researchers had several mutual visits during the project period and student exchanges.

Within the offshore wind area, MOVE has been collaborating with the Department of Wind Energy (now Wind and Energy Systems) at the Technical University of Denmark (DTU). They are very strong in onshore and offshore wind energy research and engineering, in numerical analysis and experimental testing of wind turbines for global and local response analysis of wind turbine systems and wind turbine blades. The MOVE Centre also has a strategic cooperation with University College London (UCL). The Department of Ocean Operations and Civil Engineering has also been cooperating with Massachusetts Institute of Technology (MIT) within innovation and entrepreneurship.
Training of researchers
Text: Hans Petter Hildre
Master’s degree students from the Department of Ocean Operations and Civil Engineering in Ålesund and the Department of Marine Technology in Trondheim have been involved in the SFI centre’s activities. In total 119 master’s theses as a part of SFI MOVE and several new courses have been developed.

All PhD students have been invited to participate in the NTNU School of Innovation’s programme for PhD students.

Dissemination of knowledge
Annual reports
SFI MOVE has written comprehensive annual reports. They can be downloaded from the SFI MOVE homepage.

Conferences and workshops
SFI MOVE has arranged a conference for all partners twice a year. The spring conference focused on discussion and feedback on ongoing projects. These conferences have been combined with workshops about key topics in SFI MOVE. The autumn conference focused on project results and planning of next year’s project activities.

Between 60–80 people have attended each conference. The conferences took place online during the Covid period.

PhD
SFI MOVE had 14 PhD students (including associated PhD students) and 9 postdocs. The PhDs are listed below. See Appendix 2 for details.

Research reports
Reports developed as part of SFI MOVE are stored at https://www.ntnu.edu/move and available to all SFI MOVE partners. In particular, the reports for hydrodynamic coefficients for subsea structures deserve special mention.

Software
Software developed as a part of SFI MOVE is stored at https://www.ntnu.edu/move and available for all SFI MOVE partners. We would particularly like to mention our software for data driven model tuning, vessel shielding effects, short-term predictions and on-board decision support system architecture, splash zone hydrodynamics, and parametric seakeeping optimization tool.

Publication (key numbers)
278 journal papers, conference papers and other publications are among the outputs from SFI MOVE. See Appendix 3 for a list of publications.

Arena and simulation centre for marine operations
The vision of establishing a leading research and innovation centre for demanding marine operations was a key statement defined at the beginning of the SFI MOVE project. A central element of this vision was to establish an “arena for research and industrial cooperation within demanding marine operations”. Establishment of a leading research and innovation centre for demanding marine operations was further detailed in the plan for the second period.

SFI MOVE has established a centre at NTNU in Ålesund. The centre has key technology for virtual prototyping of marine operation and has been important for full-scale testing. Digital twin technology has been tested for the NTNU research vessel Gunnerus. The idea of moving the simulations closer to the operations has been tested and trade-off simulations in case of changed weather conditions have been tested.

Background Reports
Effects of centre

Illustration of instrumentation of Fjord Laboratory in Ålesund.
Norway is one of the world’s largest maritime offshore nations and has been a major player for more than 150 years. Shipowners are especially active within shipping areas like offshore service vessels, fisheries, and aquaculture. Offshore wind service is a growing business in Norway, and major offshore wind developments in the North Sea is in planning. Marine operations are a common dimension in all these segments. SFI MOVE is a contribution to establish new methods, tools and facilities for marine operations and Norwegian maritime industry.

SINTEF Ocean conducts research and innovation related to ocean space. Our ambition is to continue Norway’s leading position in marine technology and biomarine research. Many of the challenges of modern society can be solved through sustainable use of the ocean. SINTEF Ocean has extensive expertise in the field of hydrodynamics and cybernetics, which have been key areas of focus in SFI MOVE. Participation in major research centres such as MOVE is crucial to our strategy and activity related to marine operations and fits well with SINTEF’s vision “Technology for a Better Society”. SINTEF Ocean has conducted research on ships and ocean structures for more than 80 years. The MOVE project has given us the opportunity to expand our collaboration with NTNU and attract new generations of talents within marine technology.

The Norwegian Ocean Technology Centre will have the following laboratories:
• The Ocean Basin Laboratory
• Seakeeping and Manoeuvring Basin
• Machinery Laboratory
• The Marine Structures Laboratory
• Student Laboratories
• The Fjord Laboratory

The Norwegian Ocean Technology Centre includes Fjord Laboratory, which consists of several facilities with advanced research equipment and sensors that are in Trondheimsfjorden, and off the coast of Hitra/Frøya, and Ålesund.

The laboratories give researchers and businesses the opportunity to test new solutions in model trials before they are tested on a full scale and are necessary to reduce the risk before the solutions are put into use. Computer simulation is also an important part of the centre’s operations. Through the interaction with physical experiments, various digital simulation models are validated and improved.

• Subsea robots and subsea infrastructure
• Autonomous ship and ship operations
• Aquaculture
• Marine observatory and environmental research
• Ship operations research
• Digitalization in the ocean space: models, monitoring, simulations, integration of sensor and communication platforms
• Ocean energy: wind and wave energy

Through the R&D collaboration in SFI MOVE, SINTEF Ocean, together with the partners, has created innovative cooperative teams and spin-off projects. For instance, the knowledge and methods developed in on-board decision support systems will be built on and continued in the NorthWIND Centre for Environment-friendly Energy Research (FME) for the application of gangway operations for offshore wind service operations vessels. The long-term effort of SFI MOVE also allowed us to execute strategic and targeted development of new numerical methods that have significantly improved our state-of-the-art software, SIM. O. Tools for data driven model tuning, vessel shielding effects, short-term prediction, and splash zone hydrodynamics have been developed and tested. Co-simulation capabilities have been tested. A parametric seakeeping optimization tool has also been developed. The on-board decision support system architecture may be a next-generation tool used in real time during operation.

SFI MOVE has established a centre, Arena, at NTNU in Ålesund. The centre has key technology for virtual prototyping of marine operations and has been important for full-scale testing. Digital twin technology has been tested for the NTNU research vessel Gunnerus. The idea of moving the simulations closer to the operations has been tested and trade-off simulations in case of changed weather conditions have been tested.
The overall objective for SFI MOVE is to facilitate marine operations in a commercial and cost-efficient manner, thereby contributing to positioning the Norwegian maritime industry towards the market of such operations worldwide. As operations become more extensive, there is a growing need for all-year marine operations. This need will significantly impact technology, operational procedures, and costs, and will require very different solutions depending on the environment in which you are operative.

Marine operations are designed, simulated, and planned long before the operation is carried out. Parameters are assumed for the type of vessel, load condition, wind, waves, lifted objects' behaviour in air and sea, etc. The simulation results show that the operation can be carried out if a given sea state is not exceeded. Therefore, simulations are based on a series of assumptions and uncertainties. Significant safety margins are needed to compensate for these uncertainties. How can we reduce this uncertainty and then reduce Waiting on Weather (WoW)?

In SFI MOVE, we have been working on reducing Waiting on Weather by bringing the analyses close to the operations. I think on-board simulations will be the next step in simulation of marine operations: Real-time simulations considering real met-ocean and ship conditions. Short- (0-2 minutes), medium- (hours) and long-term (more than 72 hours) predictions of met-ocean, ship responses as well as in parameters limiting the marine operations. Digital twins are the next step in simulation technology allowing real-time input from sensors into the simulation algorithms.
The installation process both for fixed and floating wind turbines have involved challenging and complex dynamic problems with a high degree of interdisciplinary achievements (nonlinear hydrodynamics, complex multibody dynamics, and advanced control strategies of hydraulically driven winches).

The interdisciplinary problem has motivated us to take advantage of a co-simulation approach where the different parts of the complex dynamic problem are modelled with high fidelity in separate domain calculations (following the idea of Functional Mock-up Units (FMUs), and then information is shared between all the units through a Functional Mock-up Interface (FMI). This is a very promising approach that not only enables high fidelity simulations in separate domains and shares only the essential information between the different units, but also allows for proprietary information to be kept within a black box if a vendor wishes to conceal the technology’s secrets.

The work and cooperation have been truly fascinating and has sparked considerable attention also internationally. We have been invited to talk about the work to conferences abroad (e.g., IMCA lifting and rigging seminar) and invited to join an international forum for developing a sustainable blue economy towards carbon neutrality.

A lot of good work has been done on a wide range of research topics as part of SFI MOVE. The work on collecting, establishing, and documenting hydrodynamic coefficients for different structures and structural components is one example that is believed to have great value for the industry from day one. Furthermore, on the topic of development of new numerical models and analysis procedures, I think the work on shielding effects, splash zone hydrodynamics, and tuning of vessel models should be mentioned. A significant effort has also been invested in developing efficient and robust methods for on-board data collection and distribution. That said, within the “On-board Decision Support System (ODSS)” topic, there is still a lot of work to be done to fulfill the vision. If you pass unphysical data to a numerical model, even the most robust model will fall over. Hence, in an ODSS setting, numerical robustness to unphysical data is key. Furthermore, computational speed is also important; you lose if your ODSS solution means that the marine operation needs to wait for the calculations/requires the marine operation to wait for the calculations. Traditionally, to avoid passing unphysical data to the computations, raw data is typically carefully filtered in advance before passing it to the processing chain. This filtering process also takes time, of course. In the world we live in, with all its artificial intelligence (AI) and machine learning (ML), maybe it is time to think differently when developing numerical models for real-time analysis applied to live data? If the numerical algorithms had a built-in ability to avoid trying to process unphysical data, to my mind that would be a good approach. And the algorithms must be faster than real-time, of course. Maybe next-generation ODSS’s should be built based on numerical algorithms with inherent data awareness (DA) and data intelligence (DI), just a thought as we now close out SFI MOVE.

The work we did within remote operations and dispersed teams provided use cases for real-time testing of our digital twin and remote operation centre. These use cases and simulator set-ups were developed in close collaboration with our industry partners and have provided insights into challenges and opportunities for utilizing such technological solutions within our industry.

The research activities have stimulated project ideas related to utilization of ROC and cyber security challenges related to remote operations. Amongst other things, we are planning for a project proposal related to how we can use remote operation centres and digital twin technology to enhance efficiency in the traditional shipping fleet.

As part of SFI MOVE, different techniques for ship hydrodynamic model updating based on monitored data was investigated in order to realize the concept of response-based marine operations. Part of this was the treatment of the ship model parameters as stochastic variables, applying discrete Bayesian updating to get a best possible fit to monitored data and the concept of applying surrogate models to speed up the model update computation.

These research activities inspired the Slender Structures Research Group at the Department of Marine Technology to apply for the Research Council of Norway project 308832 (PRAI: Predicting Riser-response by Artificial Intelligence) in cooperation with SINTEF Ocean and SINTEF Digital. The project is ongoing and focuses on investigating different alternative algorithms for model updating, hybrid modelling and uncertainty estimation for integrity management of riser systems.
Conclusions

Text: Hans Petter Hildre
The success of SFI MOVE is a result of collaboration between research by NTNU and SINTEF and industrial partners. This collaboration includes PhD students, postdoctoral students and master’s degree students.

The SFI centre model is working very well with respect to achieving cooperation between research partners. Ålesund University College was merged into NTNU in 2016 and organized as part of the Faculty of Engineering in 2017. SFI MOVE has played an important role in developing related research activities in Ålesund and cooperation with the Department of Marine Technology in Trondheim. SFI MOVE also played an active role in establishing SINTEF Ålesund in 2017. The Head of SINTEF Ålesund, Henning Borgen, was also the project leader in SFI MOVE.

A challenge in an 8-year project is to adapt to rapidly changing industrial needs. PhD work and research activities are processes that need several years to complete. It is therefore hard to change research strategy or cover short-term needs.

SFI MOVE made innovation plans in close collaboration with the industry and then developed these plans into one- and three-year plans. This approach worked well in the transition between period one and two in the project but did not work very well for shorter modifications. The set-up with PhDs linked to professors over 8 years also complicates the opportunities to adapt to changed industrial needs.

With research partners in several locations, regular communication and interactions were very important for the management. A tight management research group with weekly meeting was a key element to achieve common understanding and goals.

SFI MOVE will not apply for a new SFI project within marine operations. The focus in the years to come will be on implementation of research results, building practical tools and methods for the industry.

Appendix 3 – List of Publications

### Publications 2015–2023

#### 2015

**Pan, Yushan; Finken, Sisse; Komandur, Sashidharan.**

**Pan, Yushan; Finken, Sisse.**
*Complex Systems, Cooperative Work, and Usability.* Journal of Usability Studies 2015; Volum 10(3) s.100-112 NTNU UiO

**Ren, Zhengru; Skjetne, Roger; Hassani, Vahid.**
*Supervisory Control of Line Breakage for Thruster-Assisted Position M ooring System. 10th IFAC Conf. M anoeuvring and Control of Marine Craft; 2015-08-24 - 2015-08-26* NTNU

**Ren, Zhengru; Skjetne, Roger; Hassani, Vahid.**

**Ren, Zhengru.**

**Ren, Zhengru; Skjetne, Roger; Kjerstad, Øivind Kåre.**
*A Tension-based Position Estimation Approach for M oored Marine Vessels. 10th IFAC Conf. M anoeuvring and Control of Marine Craft; 2015-08-24 - 2015-08-26* NTNU

**Skjetne, Roger.**
*Determining ice loads for OSVs. 6th Annual seminar on Design and Operation of OSVs for Ice and Cold Climates; 2015-11-30 - 2015-12-01* NTNU

**Thorsen, Mats Jørgen; Sævik, Svein; Larsen, Carl Martin.**
*Fatigue damage from time domain simulation of combined in-line and cross-flow vortex-induced vibrations.* Marine Structures 2015; Volum 41. s.200-222 NTNU

**Zhou, Chongyao; Sævik, Svein; Ye, Naiquan; Ji, Guomin.**
*Combined in-line and cross-flow vortex-induced vibrations. Marine Structures 2015; Volum 108* NTNU

**Yang, Xu; Sævik, Svein; Sun, Liping.**
*Numerical analysis of buckling failure in flexible pipe armor wires.* Ocean Engineering 2015; Volum 108. s.594-605 NTNU

**Zhou, Chongyao; Sævik, Svein; Ye, Naiquan; Ji, Guomin.**

**Zhou, Chongyao; Sævik, Svein; Ye, Naiquan; Ji, Guomin.**

### 2016

**Sandvik, Peter Christian; Solaa, Frøydis; Firoozkoohi, Reza.**
*Hydrodynamic forces on complex subsea structures.* Marine Operations Specialty Symposium (M OSS 2016); 2016-09-20 OCEAN

**Agusta, Arifian; Ji, Guomin; Sævik, Svein.**

**Chu, Yingguang; Pedersen, Birger Skogeng; Zhang, Houxiang.**

**Gao, Zhen; Moan, Torgeir; Wan, Ling; Michailidis, Konstantinos.**
*Comparative Numerical and Experimental Study of two Combined Wind and Wave Energy Concepts.* Journal of Ocean Engineering and Science 2016; Volum 1(1). s.36-51 NTNU

**Guachamin Acero, Wilson Ivan; Gao, Zhen; Moan, Torgeir.**
*Assessment of the Dynamic Responses and Allowable Sea States for a Novel Offshore Wind Turbine Tower and Rotor Nacelle Assembly Installation Concept Based on the Inverted Pendulum Principle.* Energy Procedia 2016; Volum 94. s.61-71 NTNU

---

Pan, Yushan.
*A ten-minute talk - fieldwork stories.* Høgskolen i Ålesund 2015 25 s. NTNU UiO

Pan, Yushan.

Pan, Yushan.*

---

**Pan, Yushan; Komandur, Sashidharan; Finken, Sisse.**

**Pan, Yushan; Finken, Sisse.**
*Complex Systems, Cooperative Work, and Usability.* Journal of Usability Studies 2015; Volum 10(3) s.100-112 NTNU UiO
Guachamin Acero, Wilson Ivan; Li, Lin; Gao, Zhen; Moan, Torgeir. Methodology for assessment of the operational limits and operability of marine operations. Ocean Engineering 2016; Volum 125. s.308-327 NTNU

Gutsch, Martin; Sprenger, Florian; Steen, Sverre. Influence of Design Parameters on Operability of Offshore Construction Vessels. 111. Hauptversammlung der Schiffbautechnischen Gesellschaft e.V.; 2016-11-16 - 2016-11-18 OCEAN NTNU

Jin, Jingzhe; Solaas, Frøydis. Comparison of direct and stationary approach in prediction of lift wire tension in splash zone crossing operation. Marine Operations Specialty Symposium (MOSS 2016); 2016-09-20 - 2016-09-21 OCEAN

Kyllingstad, Lars Tandle. Simulation technology and virtual prototyping as a common approach from design to operation. MOVE Autumn Conference 2016; 2016-10-18 -2016-10-19 OCEAN

Kyllingstad, Lars Tandle. Slitloring av maritime systemer. Maritime innovasjonssam og utvikling av numerisk modelltank inkludert valg av maskinløsninger; 2 016-11-21 - 2016-11-21 OCEAN

Li, Lin; Guachamin Acero, Wilson Ivan; Gao, Zhen; Moan, Torgeir. Assessment of Allowable Sea States During Installation of OWT Monopiles with Shallow Penetration in the Seabed. Journal of Offshore Mechanics and Arctic Engineering 2016; Volum 138 (4) Suppl. 041902. NTNU

Longva, Vegard; Sævik, Svein. On prediction of torque in flexible pipe reeling operations using a Lagrangian-Eulerian FE framework. Marine Structures 2016; Volum 46. s.229-254 NTNU

Ommani, Babak; Kristiansen, Trygve; Berget, Kjetil; Sandvik, Peter Christian; Faltinsen, Odd Magnus. Investigation on Moonpool Blockage by Box Shaped Object Close to Free Surface. 3rd International Conference on Violent Flows (VF-2016);2016-03-09 - 2016-03-11 OCEAN NTNU

Appendix 3 – List of Publications

Ren, Zhengru; Skjetne, Roger.
A Tension-based Position Estimation Solution of a Moored Structure and its Uncertain Anchor Positions. The 10th IFAC Conference on Control Applications in Marine Systems (CAMS 2016); 2016-09-13 - 2016-09-16 NTNU

Ren, Zhengru; Skjetne, Roger.
A Tension-based Position Estimation Solution of a Moored Structure and its Uncertain Anchor Positions. IFAC-PapersOnLine 2016 ;Volum 49.(23) s.251-257 NTNU

Ren, Zhengru; Skjetne, Roger.
An On-site Current Profile Estimation Algorithm for a Moored Floating Structure. The 10th IFAC Conference on Control Applications in Marine Systems (CAM S 2016); 2016-09-13 - 2016-09-16 NTNU

Sandvik, Peter Christian; Solaas, Frøydis; Firoozkoohi, Reza.
Hydrodynamic forces on complex subsea structures. Some results from a Norwegian research based innovation program... Marine Operations Specialty Symposium (MOSS 2016); 2016-09-20 OCEAN

Tang, Meng.
The Architecture of deep Sea Mining Lift System. Workshop on Ocean Mining 11th May 2016; 2016-05-11 - 2016-05-11

Thorsen, Mats Jørgen; Søvik, Svein; Larsen, Carl Martin.
Time domain simulation of vortex-induced vibrations in stationary and oscillating flows. Journal of Fluids and Structures 2016 ;Volum 61. s.1-19 NTNU

Værnø, Svenn Are Tutturen; Brodtkorb, Astrid H.; Skjetne, Roger; Sørensen, Asgeir Johan.
An Output Feedback Controller with Improved Transient Response of Marine Vessels in Dynamic Positioning. IFAC-PapersOnLine 2016 ;Volum 49.(23) s.133-138 NTNU

Wang, Hao; Fossen, Sindre; Han, Fang; Hameed, Ibrahim A.; Li, Guoyuan.

Wang, Hao; Zhuge, Xu; Strazdins, Girts; Wei, Zheng; Li, Guoyuan; Zhang, Houxiang.

Xu, Jiafeng.
A Marine Simulation Framework and A Dual Quaternion Variational Integrator. MOVE Autumn Conference 2016; 2016-10-18 - 2016-10-19 NTNU

Xu, Jiafeng; Halse, Karl Henning.
Dual Quaternion Variational Integrator for Rigid Body Dynamic Simulation. arxiv.org 2016 27 s. NTNU

2017

Challabotla, Niranjan Reddy.
Model development for ocean mining lift system. OCEAN WEEK 2017; 2017-05-03 - 2017-05-05 NTNU

Dai, Tianjiao; Søvik, Svein; Ye, Naiquan.
Friction models for evaluating dynamic stresses in non-bonded flexible risers. Marine Structures 2017;Volum 55. s.137-161 NTNU OCEAN

Guachamin Acero, Wilson Ivan; Gao, Zhen; Moan, Torgeir.

Guachamin Acero, Wilson Ivan; Gao, Zhen; Moan, Torgeir.
Friction models for evaluating dynamic stresses in non-bonded flexible risers. Marine Structures 2017;Volum 55. s.137-161 NTNU OCEAN

Halse, Karl Henning.
Offshore Wind Project 2017 - Innovative Installation of Floating Wind Power Systems. MOVE autumn conference 2017; 2017-11-22 NTNU

Halse, Karl Henning.
Project 5 - Offshore Wind. MOVE Spring Conference 2017; 2017-04-05 - 2017-04-05 NTNU

Hatledal, Lars Ivar; Zhang, Houxiang; Halse, Karl Henning; Hildre, Hans Peter.
